

Reshaping Adolescents' Gender Attitudes: Evidence from a School-Based Experiment in India*

Abstract

Societal norms about gender roles perpetuate the economic disadvantages facing women in many developing countries. This paper evaluates an intervention aimed at eroding support for restrictive gender norms, specifically a multi-year school-based intervention in Haryana, India, that engaged adolescents in classroom discussions about gender equality. Using a randomized controlled trial, we find that the intervention improved adolescents' gender attitudes by 0.25 standard deviations, a sizable effect in comparison to other correlates of their attitudes such as their parents' attitudes. Program participants also report more gender-equitable behavior; for example, boys report helping out more with household chores.

Keywords: Gender equality, preference formation, social norms, persuasion

Vrinda Kapur provided outstanding management of the research project. We thank Sachet Bangia, Rachna Nag Chowdhuri, Alejandro Favela, Vrinda Kapoor, Lydia Kim, Suanna Oh, Priyanka Sarma, Niki Shrestha, Anantika Singh, and Rachita Vig for excellent research assistance, and Alice Eagly for many helpful suggestions. We are grateful to International Initiative for Impact Evaluation, J-PAL Post-Primary Education Initiative, and International Growth Centre for funding data collection. The trial is registered in the AEA RCT Registry (AEARCTR-0000072).

1 Introduction

Gender inequality exists in every society but is especially severe in many developing countries: Women and girls have fewer educational opportunities, less autonomy over marriage and fertility, more restrictions on labor force participation, and even a lower likelihood of being born than their male counterparts (Duflo, 2012; Jayachandran, 2015). Many of these gender gaps are stagnant despite economic progress, suggesting that economic development on its own is unlikely to close them.

Recent work has drawn economists' attention to the importance of cultural norms in perpetuating gender gaps (Bertrand et al., 2015; Alesina et al., 2013; Giuliano, 2017). Meanwhile, there is also promising evidence that even centuries-old norms are amenable to change. Reserved seats for female politicians reduce gender-biased attitudes in India (Beaman et al., 2009), and television programming can change fertility preferences (Jensen and Oster, 2009; La Ferrara et al., 2012). These findings are part of a broader literature on how individual preferences are shaped (Becker and Mulligan, 1997; Bowles, 1998).

This paper focuses on a direct attempt to reshape gender attitudes through discussion and persuasion. We evaluate a school-based program in the state of Haryana, India, for seventh to tenth graders. The program centered around classroom discussions about gender equality that were held regularly (a 45-minute session every three weeks for two and a half school years). The sessions taught facts and endorsed gender equality, and as importantly, prompted students to reflect on their own views and their society's. Discussion topics included gender roles at home, girls' education, women's employment outside the home, and harassment. Some sessions taught communication skills to help students convince others of their views and, say, persuade their parents to permit them to marry at a later age. The program's messaging combined a human-rights case for gender equity with pragmatic reasons to value women, such as their economic contributions. The reason for targeting secondary school students is that adolescence is a critical time in the development of morality and formation of identity, when people are young enough to still have malleable attitudes but mature enough to reflect on complex moral questions (Kohlberg, 1976; Markus and Nurius, 1986). The intervention was designed and implemented by a non-profit organization with extensive experience in gender-equality programming. The Government of Haryana allowed the non-profit to lead these classes during the regular school day.

As context, gender inequality is pronounced in India. While boys and girls start sec-

ondary school at the same rate, only 0.73 girls enroll in tertiary schooling for every boy (World Bank, 2010). Early marriage and childbearing are common, and women face life-long barriers to access to healthcare (Pande, 2003; Jayaraman et al., 2014), mobility and autonomy (Calvi, 2016), and labor force participation (Afridi et al., 2017; Field et al., 2010). Selective abortion of female fetuses is widespread (Sen, 1990; Jha et al., 2006). India’s sex ratio among children age 0 to 6 years is 1.09 boys per girl; Haryana’s sex ratio of 1.20 is the most male-skewed among Indian states (Govt. of India, 2011).

We implement a randomized controlled trial across 314 government secondary schools in four districts, with data collected for roughly 14,000 students. We examine how the program changed students’ gender attitudes, aspirations, and behaviors (our three pre-specified primary outcomes). By attitudes, we mean views about what is right and wrong such as whether it is wrong for women to work outside the home. By aspirations, we mean goals for one’s own life, for example to pursue higher education or a career; while the program was aimed at changing both boys’ and girls’ attitudes, any impacts on aspirations should be concentrated among girls. Finally, for behaviors, we mean those that are influenced by gender norms such as chores done at home and frequency of interaction with opposite-gender peers. While attitude change could be sufficient to prompt behavior change, many moderating factors might stand in the way. A girl who asks that her burden of household chores be reduced might simply be ignored by her parents. A boy who now believes that he should help out with chores might still feel that the social sanctions for doing so are too costly. Thus, we also examine whether the program changed perceptions of social norms and how the home environment mediates the intervention’s effects.

We find that the intervention improved gender attitudes, measured with an index that aggregates several survey responses, by 0.25 standard deviations. This coefficient is robust to a number of tests, including to the possibility that the intervention induced students to disingenuously offer more socially desirable survey responses. One way to benchmark the effect size is to use the correlation between parents’ and children’s gender attitudes; the intervention’s impact is much larger than the change associated with having a parent whose attitudes are one standard deviation more gender equitable. The intervention also produced more gender-equal behavior such as increased interaction at school with the opposite sex. However, the intervention did not have a significant impact on girls’ educational and professional aspirations (which are quite high to begin with).

The program impacts are similar for students whose parents have more versus less gender-progressive views and for boys versus girls. Behavior change is larger for boys, however. For example, boys report doing more household chores, but girls do not report doing less. This asymmetry is consistent with behavior change requiring both wanting and being able to change, and there being more external factors constraining girls' behavior.

Our study contributes to the literature on endogenous preferences, which includes past work on the formation of gender-related preferences. Besides political quotas (Beaman et al., 2009) and television (Jensen and Oster, 2009; La Ferrara et al., 2012), other factors that have been shown to make attitudes more gender-progressive include mothers' labor force participation (Fernandez et al., 2004), having daughters (Washington, 2008) or sisters (Healy and Malhotra, 2013), and serving with women in the military (Dahl et al., 2017).

We also add to the literature on persuasion, that is, communication intended to change preferences or beliefs (DellaVigna and Gentzkow, 2010). Many studies focus on efforts to influence consumer or political preferences. Closer to our work are studies on attitude change about intimate partner violence (Green et al., 2017), concealing one's HIV status from sexual partners (Banerjee et al., 2017), the mentally ill (Evans-Lacko et al., 2013), and racial minorities (Donovan and Leivers, 1993), and studies about altering perceptions about social norms about discrimination (Paluck, 2009). Also related is Cantoni et al. (2017), which finds that Chinese students taught with textbooks designed to convey pro-Communist messages exhibit more pro-government views and skepticism of free markets as adults. (Indeed, one way to scale up the program we study would be to incorporate the material into textbooks.)

Finally, our study contributes to the vast literature on gender gaps and determinants of women's agency in developing countries. Recent work in India has studied cultural incentives to have sons (Bhalotra et al., 2018; Jain, 2014); how parents' desire to have sons affects girls' health (Jayachandran and Kuziemko, 2011; Jayachandran and Pande, 2017); how the diffusion of ultrasound technology affected the sex ratio (Bhalotra and Cochrane, 2010); financial incentives to have daughters (Anukriti, 2017); information on the returns to girls' education (Jensen, 2012); improving women's financial access (Field et al., 2016); and more. Other related recent work includes Buchmann et al. (2017) on girls' empowerment training and financial incentives to delay marriage in Bangladesh and Ashraf et al. (2018) on teaching negotiation skills to girls in Zambia.

2 Description of intervention

The project emerged from the Government of Haryana’s interest in testing policies to narrow gender gaps. The intervention was designed and implemented by Breakthrough, a human rights organization with experience in social change programs. The participants were the cohorts that started in grades 7 and 8 in the academic year 2014-15, and the program ran from April 2014 to October 2016 (i.e., one cohort participated in the program in grades 7, 8 and half of 9, and the other cohort participated in grades 8, 9 and half of 10). Grades 7 to 10 have fairly high enrollment and low dropout, implying that the program could reach a large proportion of the underlying age cohorts and that attrition due to dropout would be limited (significant dropout occurs after grade 10) (DISE, 2011).¹

The objective of the program was to create awareness of gender-based discrimination, change dominant gendered perceptions and promote gender equitable attitudes, raise aspirations, and provide tools to participants to be able to translate attitude change and greater aspirations into behavior change. By changing fundamental gender attitudes, the program aimed to influence a wide range of behaviors related to female education, mobility, work, marriage and fertility, for both female participants and male participants’ female family members (e.g., future wives).

The program emphasized both economic and human rights reasons for valuing girls. For instance, the intervention activities informed participants about benefits of girls’ education such as how outcomes for children improve when the mother is more educated. The hypothesis is that this information causes girls to update their beliefs and place higher value on staying in school longer, and for both boys and girls to place higher value on educating their daughters down the road. The messaging also emphasized that equal opportunity for education for girls is a basic human right.

To ensure that the intervention would be widely accepted, Breakthrough engaged with multiple stakeholders at the state, district, and block levels, orienting and gathering input from various education officials, school principals, and teachers. This helped them design a program that might ultimately be integrated into the regular school curriculum.² The central

¹The enrollment rate in grades 6 to 8 was 77% for boys and 80% for girls in 2009-2010. Dropout is 4.1% between grades 7 and 8, although some students transfer to private schools.

²One approach for scale-up would be for the government to hire special-purpose teachers, each covering several schools, who deliver the curriculum, or to incorporate the content into textbooks and standardized school assignments.

feature of the program was interactive classroom sessions led by a Breakthrough facilitator. Other elements of the program included teacher training, youth clubs, school activities, and a media and communications campaign.

The program comprised 26 sessions, each 45 minutes long, conducted over two and a half school years. Breakthrough facilitators visited each school roughly every three weeks. Discussion topics included gender identity, values, aspirations, gender roles and stereotypes, and recognition and tolerance of discrimination. For example, one session focused on household chores. Students broke out into groups and listed whether males or females did various chores in their households. They then reconvened and discussed the answers. When the pattern emerged that women and girls did most of the chores, the facilitator asked why that was and whether it was fair. The class discussed why women do the cooking at home, but men are cooks in restaurants, with the latter role earning more prestige in society. A few of the sessions aimed to impart skills such as public speaking, communication between the genders, leadership, and self-efficacy. These skills could help translate gender-equitable attitudes into behavioral change. For instance, girls might be able to negotiate greater independence with their parents, leading to more freedom of movement in the short run and greater occupational choice in the long run. Through these topics, plus homework assignments such as writing stories, recording observations, and encouraging dialogue with family members, and some activities outside the classroom such as street theater and optional Breakthrough clubs, students explored gender identity and stereotypes, gained a better understanding of gender inequities and their consequences, understood their rights and entitlements, and were encouraged to communicate and act on what they had learned.

3 Study design and data

3.1 Experimental design

We conduct a randomized evaluation of the gender attitude change program, with randomization at the school level, using a sample of 314 government schools across Sonapat, Panipat, Rohtak and Jhajjar districts in the north Indian state of Haryana. The study districts are adjacent to or near to New Delhi.³

The sample size of 314 schools was chosen to be able to measure the immediate impact of

³The 2011 child sex ratio in Sonapat was 1.25, 1.19 in Panipat, 1.22 in Rohtak and 1.28 in Jhajjar.

the program on gender attitudes, aspirations and behavior, as well as on long-term outcomes such as educational attainment, occupational choice, marriage, and fertility. Schools were selected from the universe of 607 government-run secondary schools that offered grades 6 through 9 in the four districts, with at most one school per village included in the sample. Details on the selection of the sample schools is provided in the appendix. Of the 314 schools, 59 enroll only girls, 40 enroll only boys, and the remaining 215 are co-ed. Schools have an average of 84 students per grade.

We randomly selected 150 of the sample schools to be in the treatment group; the remaining 164 serve as control schools. Appendix Figure 1 shows the four study districts and the schools assigned to the treatment and control groups. The randomization was stratified by district, co-ed status of the school, school size, and distance to the district headquarters. Table 1 reports baseline characteristics of schools by treatment status. The first panel confirms that the two samples are balanced on various school characteristics such as co-ed status, urban/rural, number of male and female students, and number of teachers.

3.2 Data collection

We measure attitudes, aspirations, behavior, and a rich set of individual and household characteristics through baseline and endline surveys. The baseline survey was conducted between August 2013 and January 2014, covering 14,810 students and 5,483 parents. The endline survey was conducted between November 2016 and April 2017, covering 13,945 students, which represents a 94.2% resurvey rate.

To select students within schools for the sample, we randomly chose among those whose parents gave consent for their child to participate in the study and who personally agreed to participate, stratifying by gender and grade in the ratio Female 6th:Male 6th:Female 7th:Male 7th of 3:2:2:2. We surveyed more girls than boys because female enrollment is higher than male enrollment in government schools, and we sampled more grade 6 girls than grade 7 girls because we expected lower attrition for younger grades.⁴ To be in the study, the student also needed to be at school on the baseline survey day.⁵ The 35-minute-long baseline survey took place on the school premises.

Table 1 summarizes key characteristics for the sample at baseline. The average age

⁴Parents are more likely to send their sons than daughters to private schools. Also, wealthier families use private schools, so the boys in government schools are from relatively poorer families than the girls.

⁵Chronically absent students and those whose parents did not provide consent are underrepresented in the data. Anecdotally, lack of consent was usually due to the student losing or forgetting the form.

for both boys and girls is between 11 and 12 years.⁶ Religious and caste variables line up with the overall demographics for these districts, as reported in the 2011 Census (Govt. of India, 2011). Characteristics, including baseline gender-related attitudes, aspirations, and behavior, are balanced between the treatment and control groups. An F-test of joint significance fails to reject balance between the subsamples.

We measure gender attitudes through direct questions on female and male roles and rights (e.g., whether women should go to college and work outside the home) and gender norms (e.g., the appropriate age of marriage for girls). We also measure attitudes via questions about a vignette on investing in a son’s or daughter’s education. Gender attitudes in the sample are quite regressive at baseline. For example, 80% of boys and 60% of girls believe that a woman’s most important role is being a good homemaker. This pattern that girls’ endorse gender-discriminatory views but to a lesser extent than boys do is seen for most of our attitude questions (see Appendix Table 1).

Responses to several questions were aggregated into a gender attitude index, the construction of which was pre-specified.⁷ The appendix provides more detail on how the attitudes index and other indices were constructed.

The survey also included a module on aspirations for education and occupation; responses were aggregated into an aspirations index. Complementing this were questions on gender-equitable behavior among students – students’ comfort with and interaction with the opposite gender; engagement with household chores; autonomy; and encouragement given to girls and women in their lives to pursue education and careers.

A key concern when examining attitudes is that students might report insincere gender-progressive attitudes or behaviors because they are aware of being studied. If such misreporting is more prevalent among treated students—who know they are part of a program trying to change their gender attitudes—this would upward bias our findings. Therefore, we included at baseline a Crowne-Marlowe survey module designed by psychologists to measure the respondent’s propensity to give socially desirable answers (Crowne and Marlowe, 1960). We use this social desirability measure to assess whether our results are driven by students’ desire to make a favorable impression on the surveyor.

⁶Baseline data is missing for one school because we mistakenly collected it in a different school in the village. The intervention and endline data collection were collected in the correct, originally sampled school.

⁷The pre-analysis plan was posted to the AEA RCT Registry in November 2016 at the beginning of endline data collection. It specified the primary outcomes and how they would be constructed, secondary outcomes, heterogeneous effects we would examine, and procedure for choosing control variables.

To understand how parental attitudes influence program impacts, one parent of a random 40% subsample of the surveyed students participated in a survey at the student’s home; we selected at random whether to interview the father or the mother.⁸ Parents answered questions on their gender attitudes among other topics.

Table 1 summarizes characteristics of the parents. The mean age is 35.2 years for mothers and 40.2 years for fathers. There is a high illiteracy rate for mothers, reflecting the low level of female schooling in the parents’ generation. A quite small proportion (29.2%) of mothers work outside the home, which is consistent with low female labor force participation rates in India.

Endline data collection began in November 2016, a month after the intervention ended, and concluded in April 2017. It was conducted primarily in the same school where the baseline was conducted (75.6% of endline respondents). A number of students had moved to a different school, either in the same or a different village, or dropped out of school. These students were surveyed at home (24.3% of endline respondents). If the student had moved to another village that was far from the survey districts, we conducted a truncated phone survey (0.11% of endline respondents).⁹ We were able to resurvey 13,989 baseline respondents at endline, corresponding to an attrition rate of 5.8%. Appendix Table 3 shows that sample attrition is unrelated to treatment status, and that attrition in the treatment versus control groups is not differential based on baseline attitudes, aspirations, or behavior.¹⁰

The 40-minute endline survey repeated a number of questions on gender attitudes and behavior from the baseline, and we added new questions measuring attitudes, such as towards occupational decisions, marriage, fertility and social norms. Responses to individual questions are aggregated into indices of gender attitudes, aspirations, and behavior that are our main outcomes.

⁸Budget constraints are the reason that only 40% of households and one parent were chosen.

⁹Appendix Table 2 summarizes participants’ schooling status at endline: 81.6% were enrolled in the same school as baseline, 7.9% had dropped out of school, and the remainder had changed schools. The table also reports the treatment group’s engagement with the Breakthrough program; 79% were aware of the program activities, and 73% recalled participating in one or more activities. Appendix Table 3 shows that treatment status is not significantly correlated with endline survey location.

¹⁰Appendix Table 4 details the reasons for attrition, which include permanent or long-term migration, death or poor health, refusal to participate by the student or parent, and the survey team’s inability to find the respondent at the time of an appointment.

4 Empirical specification and results

The intervention is hypothesized to make participants’ attitudes less discriminatory against females, raise girls’ aspirations, and increase gender-equitable behavior. This section describes the estimation strategy used to test these hypotheses and presents the results.

4.1 Specification

We use a dataset with one observation per student and estimate the following ordinary least squares regression specification:

$$Y_{ij} = \beta_0 + \beta_1 Treat_j + \beta_2 Y_{ij}^0 + \beta_3 \mathbf{X}_{ij} + \epsilon_{ij} \quad (1)$$

Y_{ij} is the outcome variable measured at endline for student i in school j . The first primary outcome is a gender attitudes index. The second is an aspirations index, and the third is a gender behavior index. $Treat_j$ is a binary variable that equals 1 if the school was assigned to the treatment group, and 0 otherwise. Thus, β_1 represents the average effect of the intervention on the outcome. The outcomes are constructed so that a higher value represents more gender progressiveness, so the hypothesis is $\beta_1 > 0$.

We control for Y_{ij}^0 , the baseline analogue of the outcome. The vector X_{ij} comprises other control variables, which in our basic specification are grade-gender fixed effects and district-gender fixed effects. We also estimate an enhanced specification which controls for additional baseline student, parent, and school characteristics chosen using LASSO following Belloni et al. (2014).¹¹ We allow the error term, ϵ_{ij} , to be clustered at the school level.

4.2 Program impacts on primary outcomes

Table 2 reports the main treatment effects on gender attitudes, aspirations, and behavior using the basic specification. We find that the intervention made gender attitudes more progressive: Column (1) shows that treatment schools have a 0.256 standard deviation higher attitude index than control schools ($p < 0.01$). The coefficient is stable (0.244) when the LASSO-selected extended controls are included, as shown in Appendix Table 5.¹² To account

¹¹The appendix lists the extended control variables and the larger set of variables from which the LASSO procedure chose them.

¹²Because the results are similar with or without the extended controls, subsequent tables only present results without the extended control variables.

for potential endogenous attrition from the sample, we also estimate Lee bounds on the treatment effects (Lee, 2009). Appendix Table 6 shows that the attrition-adjusted lower bound on the point estimate is 0.239.

A key concern is that participating in the program might have made salient what the socially desirable responses to our survey questions were without changing actual views. To test for this, we construct a social desirability score using responses to a short-form Crowne-Marlowe module (conducted at baseline) that measures whether the respondent has a tendency to offer socially desirable answers. (The module asks the respondent whether he has several too-good-to-be-true personality traits such as never being jealous of others' good fortune and always admitting when he makes a mistake.) We test for heterogeneous treatment effects based on this measure; it would be worrisome if the treatment effects were driven by students with a high propensity to give disingenuous answers. Reassuringly, Table 3 shows that there are no differential treatment effects on gender attitudes by the social desirability score (SDS). Meanwhile, the main effect of having a low (i.e., below-median) SDS is quite large and negative, suggesting that there is some upward shading of responses overall and SDS is capturing this tendency. Importantly, there is no more of this shading up in the treatment group than the control group. The estimated treatment effects appear to reflect real changes in attitudes.

To benchmark the size of the program's effect on attitudes, Appendix Table 7 shows the correlation in the control group between baseline factors that might affect attitudes and endline attitudes. Being a girl is associated with a 0.69 standard deviation higher gender attitude index, whereas a one standard deviation increase in parent gender attitudes increases child gender attitudes by 0.03 standard deviations.¹³ Thus, the treatment effect is much larger than the effect of having a parent whose attitudes are one standard deviation more progressive, and approximately one third of the girl-boy gap in attitudes.

Table 2 also shows a small effect of the treatment on aspirations. The average effect of the program is 0.05 standard deviations ($p < 0.01$). However, this result is not robust to restricting the sample to respondents with below-median social desirability scores (Table 3), and moreover, we shown below that the effect is driven by boys. Thus, we interpret the data as showing no clear evidence that the intervention raised aspirations.

¹³Dhar et al. (2018) presents an arguably better benchmark using parental attitudes, comparing responses to the same set of questions for parents and students, and attitudes collected for both at baseline. A one standard deviation increase in parental attitudes increases student attitudes by 0.11 standard deviations.

The third primary outcome reported in Table 2 is behavior. Our survey included more behavior questions relevant for girls than boys (e.g., mobility outside the home), and in some cases the hypothesized behavior change is in opposite directions for boys and girls (e.g., doing more chores for boys and less for girls). Thus, we show the results separately for girls and boys including all available questions, and then pooled, where we restrict the index to the common questions and we code an increase in boys doing chores as equivalent to a decrease in girls doing chores. The gender-specific behavior index increases by 0.20 standard deviations for girls and 0.46 standard deviations for boys. Column (6) pools both genders and finds an average effect of 0.36 standard deviations. These estimates are robust among respondents exhibiting low social desirability bias (see Table 3). Thus, our analysis suggests that the intervention led to a sizable reduction in gender-biased and gender-stereotyped behavior.

4.3 Disaggregated results and heterogeneity analysis

This section disaggregates the main effects shown above and examines heterogeneity across individuals.

We begin by examining thematic sub-indices to show which specific attitudes and behaviors the intervention affected. Appendix Table 8 reports the effect of the program on four sub-indices of attitudes: towards opportunity for education, employment outside the home, women’s roles in society, and fertility behavior. These findings potentially reveal which topics students paid most attention to, which attitudes are more malleable, or where the program thrust was greatest. The effects on attitudes towards education, employment, and women’s roles are large and statistically significant, with the strongest effect on employment attitudes (0.319), followed by gender roles attitudes (0.223) and education attitudes (0.190). The effect on gender-equitable fertility attitudes is smaller (0.079), which is likely due to the Breakthrough sessions having very limited discussion of this outcome, but could also be due to such attitudes being difficult to change, or school-age participants being too distant from their own child-bearing years to absorb messages on this topic.

We next examine how the program impacts differ across individuals. Girls might be more receptive to the programs’ messages, or, the program might change boys’ attitudes more because they start out with less gender-egalitarian views and thus have more room for improvement. As reported in column (1) Table 4, we do not find a significant differential effect of the program on girls’ attitudes, on average. Column (2) examines aspirations, and although the negative interaction effect for girls (-0.043) is not significant, we cannot reject

the null of no effect on girls' aspirations. Using the behavior index based on outcomes relevant for boys and girls, we find that the program had a significantly smaller impact on girls' behavior (interaction coefficient of -0.211, $p < 0.01$), although the net effect for girls is also positive and significant.¹⁴ One interpretation of this finding is that boys and girls can adopt gender-equal attitudes with relatively equal ease, but girls face more constraints on translating their attitudes into behavior.

To better understand these gender differences in behavioral change, Appendix Table 10 examines behavior sub-indices. The intervention generated more interaction with the opposite sex for both boys and girls, with a larger impact for girls. It also led to greater mobility (i.e., walking to school alone) for girls, but had no impact on girls' decision-making power. Two specific behaviors drive the larger effect for boys on the aggregate behavior index reported above. First, boys do more household chores, but girls do not cut back on chores. This pattern is consistent with boys being able to unilaterally decide to help out more, but girls needing, and not receiving, their family's consent to do fewer chores. Second, there is a large increase for boys in encouraging female family members to pursue higher education and careers, but no such effect for girls. While the chores variable is unique (we expect opposite-signed changes for boys and girls), the findings for encouraging women to pursue education and careers points to a more general phenomenon that men face fewer constraints on their behavior than women do. Extrapolating, the program's similar impact on attitudes for males and females might translate into larger changes in long-run behavior for males.

Next, we test whether the program's effects differ for students from more progressive versus conservative families. Is the intervention a substitute or complement to parents' views in shaping children's attitudes? As shown in Columns (4) to (6) of Table 4, we do not find significant differential effects of the treatment by parents' gender attitudes, and moreover, the point estimates are small compared to the main effects. We thus have little evidence to conclude that pro-girl parent attitudes facilitate or hinder the success of the intervention.

4.4 Program impacts on secondary outcomes

We examine impacts on perceptions of social norms as a secondary outcome. Changes in beliefs about social norms could be as or more important a channel for behavior change

¹⁴This heterogeneity analysis is robust to correcting for the differential selection into the sample by wealth for girls and boys discussed in footnote 4. See Appendix Table 9.

as changes in personal attitudes (Tankard and Paluck, 2016). Conversely, we also assess how much participants view social norms as preventing them from acting on their progressive attitudes. To do so, we examine parallel questions about (1) personally holding a positive gender attitude (2) believing society has a positive gender norm in that domain and (3) personally holding a positive attitude and believing society will not oppose them if they act on it. Table 5 reports the results, first, for a norm about women’s employment. Column (1) shows that the intervention made personal attitudes about female employment more progressive by 13 percentage points, and column (2) shows that it increased the perception that others in the community hold that gender-progressive view by 5 percentage points. Meanwhile, the effect on holding the progressive attitude and believing society will be supportive (column 3) is smaller (7 percentage points) than the effect on simply holding that attitude (column (1): Some students whose own attitude changed believe that they will be hindered in acting on their views by restrictive cultural norms. Columns (4) to (6) show a similar pattern for norms about women pursuing a college education.

We also examine two other pre-specified secondary outcomes, girls’ self-esteem and awareness of gender discrimination. Appendix Table 11 shows that the intervention increased a self-esteem index by 0.12 standard deviations, but, surprisingly, as much for boys as girls. The program also led to a modest (0.069 standard deviation) increase in awareness of gender-based discrimination.

Finally, based on feedback when we presented our initial results, we collected additional data in early 2018 for a subset of our sample to objectively measure gender-related behavior in the classroom. We measured girls’ class participation, students’ views on girls’ knowledge, and students’ interaction with opposite-gender peers. Unfortunately, these analyses are underpowered, as discussed in the appendix. We do not find statistically significant treatment effects on these outcomes (see Appendix Table 12).

5 Conclusion

One approach to rooting out gender discrimination in a society is to try to directly change people’s attitudes. This paper examined whether a school-based gender attitude change intervention could succeed in making adolescents’ attitudes less discriminatory, raise girls’ aspirations, and reduce gender-biased behavior. The approach centered on having students think about and discuss gender differences and gender equality in classroom sessions

held periodically over three school years. Using a randomized trial across 314 secondary schools in Haryana, India, we find that the intervention succeeded in making gender attitudes more progressive, with an accompanying effect on gender-equal behavior but no boost in girls' educational and career aspirations.

Our setting of north India has particularly strong gender discrimination, and the impacts of a similar intervention might be either larger or smaller in places with less gender discrimination. Cross-cultural differences in how much autonomy adolescents have also mean that the extent to which attitude change translates into near-term behavior change will also vary with the context.

One direction for future research is to unpack which elements of the intervention (e.g., human rights versus economic arguments) were most effective. Doing so requires systematically varying implementation, which our research design did not do. One could also compare this program, which explicitly discussed gender equality in dedicated class sessions, to a less overt approach. For example, through assigned readings featuring empowered women or writing assignment for history class that ask students to discuss changes in women's roles in society, schools could embed gender-equality messaging and prompt reflection on these topics without explicitly positioning the assignments as about gender inequality.

Another important question, of course, is whether the effects of this program will be sustained in the long run, leading to changes in educational achievement, occupational choice, marriage, and fertility years after the intervention has ended. Based on our short-run findings, we hope to track the respondents into adulthood to examine long-run outcomes.

Table 1: Descriptive statistics: School and student characteristics at baseline

Variable	Treatment	Control	Standardized Diff
Number of schools	149	164	
Urban	0.107 [0.311]	0.073 [0.261]	0.119
School is Coed	0.698 [0.461]	0.677 [0.469]	0.045
Number of males in 6th and 7th	53.912 [48.392]	52.995 [40.152]	0.021
Number of females in 6th and 7th	66.709 [60.389]	63.078 [58.318]	0.061
Total number of teachers	17.766 [9.988]	17.173 [7.987]	0.066
Number of students	7,052	7,758	
Student's age	11.833 [1.258]	11.854 [1.246]	-0.017
Female	0.565 [0.496]	0.543 [0.498]	0.044
Hindu	0.945 [0.227]	0.953 [0.211]	-0.037
Enrolled in grade 6	0.526 [0.499]	0.521 [0.500]	0.010
Scheduled caste	0.268 [0.422]	0.285 [0.433]	-0.040
Mother's age	35.183 [4.084]	35.247 [4.272]	-0.015
Father's age	40.251 [4.568]	40.294 [4.678]	-0.009
Mother is illiterate	0.369 [0.460]	0.374 [0.461]	-0.011
Mother works full-time	0.291 [0.445]	0.292 [0.446]	-0.002
Dwelling has flush toilet	0.155 [0.362]	0.131 [0.337]	0.069
Gender Attitudes Index	0.031 [1.012]	0.000 [1.000]	0.031
Aspirations Index	0.006 [1.012]	0.000 [1.000]	0.006
Behavior Index	-0.012 [0.991]	-0.000 [1.000]	-0.012

F-stat for joint significance of above baseline student variables is 0.880

Notes. Table reports variable means and standard deviations.

Table 2: Average effects of the gender attitude-change intervention

	Gender Attitudes Index (1)	Aspirations Index (2)	Girls' Behavior Index (3)	Boys' Behavior Index (4)	Behavior Index (5)
Treated	0.250*** [0.019]	0.052*** [0.019]	0.199*** [0.031]	0.461*** [0.031]	0.323*** [0.022]
Basic controls	Yes	Yes	Yes	Yes	Yes
Extended controls	No	No	No	No	No
Observations	13989	13989	7788	6201	13989

Notes: Asterisks denote significance: $*p < .10$, $**p < .05$, $***p < .01$. All columns control for the baseline analogue of the outcome variable, grade-gender, and district-gender fixed effects. All regressions also include a variable indicating if any component of the index was missing and imputed with the gender-district-treatment average. Standard errors are clustered by school.

Table 3: Robustness check for social desirability bias

	Gender Attitudes Index (1)	Aspirations Index (2)	Girls' Behavior Index (3)	Boys' Behavior Index (4)	Behavior Index (5)
Treated	0.223*** [0.025]	0.065** [0.027]	0.189*** [0.043]	0.488*** [0.041]	0.328*** [0.028]

Basic controls	Yes	Yes	Yes	Yes
Extended controls	No	No	No	No
Observations	336	335	335	336

Notes: Asterisks denote significance: $*p < .10$, $**p < .05$, $***p < .01$. Each observation is a school-grade. We have data from 197 schools, 145 of which extend through grade 12 and 52 of which extend through grade 10 only. We are missing data for 10th graders for 4 of the schools because the exams were occurring during our visit. We also have missing data for 11th graders for 2 schools, either because the Principal did not give us permission or the boys' section did not exist. All columns control for average baseline gender attitudes index for girls and boys, average baseline behavior index for girls and boys, and grade and district fixed effects. Standard errors are clustered by school.

A Data Appendix

A.1 Sample selection and tracking

From the universe of 607 government secondary schools in the study districts, we focused on 347 schools with medium to high enrollment based on DISE (2011) data, and with low dropoff in enrollment between grades (as a proxy for attrition from the school). In villages with multiple schools, only one school per village was randomly selected. If the schools were adjacent to each other or shared a building, we considered them a single school. After initial visits, we excluded 33 schools because of chronically low actual attendance despite high official enrollment, leaving 314 schools that form the sample.

We distributed consent forms to 30,685 students. Of these, 84 percent returned the form signed by their parent or guardian. Most students who did not return a consent form said they “forgot to bring it” on the day the enumerator visited the school. Providing consent is uncorrelated with the student’s gender, which is suggestive that it is not closely related to parental gender attitudes. Our sample of students for each school is randomly selected from those returning the consent form who were present on the baseline survey day in their school and assented to participate. For the parent survey, if after multiple visits and follow-up phone calls, we could not interview the selected parent, we randomly chose a replacement household. We collected data for 2,379 fathers and 3,104 mothers. The completion rate was higher for mothers (89.6%) than for fathers (70.2%) because fathers were more often away for work during the daytime hours when the survey was conducted.

To reduce sample attrition between baseline and endline, we conducted two tracking surveys to verify respondents’ contact information in January to March 2015 (98.5% tracking rate) and February to June 2016 (93.8% tracking rate).

A.2 Gender attitudes index

The gender attitudes outcome variable is constructed by aggregating responses to a wide-ranging set of individual questions into indices (both an endline index and a baseline index). For questions that used a 5-point Likert scale, the response was first converted to a binary variable coded as 1 if the respondent answered “Strongly Agree” or “Agree” with a gender-progressive statement (or “Strongly Disagree” or “Disagree” with a gender-regressive statement), and 0 otherwise. The index is the weighted average value of the individual variables, with weights constructed by normalizing the variables to have the same standard deviation and then recovering the weights given by the inverse covariance matrix (Anderson, 2008).¹⁵ We normalize the index to have mean 0 and standard deviation in the control group. A higher value of the index means more gender equitable views.

The baseline attitude index aggregates the following survey questions.

- B1. A woman’s most important role is being a good homemaker
- B2. A man should have the final word about decisions in his home
- B3. A woman should tolerate violence to keep her family together
- B4. Wives should be less educated than their husbands
- B5. Boys should get more opportunities/ resources for education

¹⁵Some questions were asked to a random 50% of respondents to reduce the survey’s length. For missing values, the value was imputed as the sample average for the gender-district-treatment status.

- B6. Men and women should get equal opportunities in all spheres of life
- B7. Girls should be allowed to study as far as they want
- B8. Daughters should have a similar right to inherited property as sons
- B9. It would be a good idea to elect a woman as the village Sarpanch

The endline index aggregated responses to 18 questions. We also divided the attitude questions into four mutually exclusive sub-indices for use in auxiliary analyses: gender equality in education, gender equality in employment, women's roles, and fertility preferences.

Education attitudes

- E1. Wives should be less educated than their husbands
- E2. Boys should be allowed to get more opportunities and resources for education than girls
- E3. Education Vignette: If you were the head of the family whom would you have sent to the town for further studies?

Employment attitudes

- E4. A woman's most important role is to take care of her home, feeding kids and cook for her family
- E5. Men are better suited than women to work outside of the house
- E6. Work Vignette: Marriage is more important for Pooja than her job
- E7. Work Vignette: Being a teacher would be a more suitable job for Pooja
- E8. Do you think women should be allowed to work outside home?

Women's role attitudes

- E9. Daughters should have a similar right to inherited property as sons
- E10. It would be a good idea to elect a woman as the village Sarpanch
- E11. A man should have the final word about decisions in his home
- E12. A woman should tolerate violence in order to keep her family together
- E13. Parents should maintain stricter control over their daughters than their sons
- E14. Girls should attain higher education so that they find better husbands *less* Boys should attain higher education so that they find better wives
- E15. A shy demeanour makes a boy a more suitable groom *less* A shy demeanour makes a girl a more suitable bride¹⁶
- E16. When a girl laughs, she should cover her mouth *less* When a boy laughs, he should cover his mouth
- E17. At what age would you like your sister/female cousins/friends to get married *less* At what age would you like your brother/male cousins/friends to get married?¹⁷

¹⁶Only one of these two questions was asked to each respondent (determined by randomizing). We thus use the school mean rather than the individual's response. We code the question as gender-regressive if the value for demure bride is greater than a demure groom.

¹⁷We code two dummies from this – the first for saying that the age for girls > 19 and the other that the gap between boys and girls is larger than the control group median response.

Fertility attitudes

- E18. Suppose the first two children born to a husband and wife are both girls. Which of the following should they do? *less* Suppose the first two children born to a husband and wife are both boys. Which of the following should they do?¹⁸

A.3 Aspirations index

We construct a gender aspirations index that measures educational and occupational aspirations. The questions used for the baseline aspirations index were as follows.

- B1. Have you ever discussed your education goals with your parent or adult relative?
- B2. What is the highest level of education you would like to complete if finances and opportunity of the school/college are available?
- B3. What occupation do you expect to have when you are 25 years old?

The questions used for the endline aspirations index were as follows.

- E1. How many marks, according to you, will you score in the SSE 10th board examinations?
- E2. Have you ever discussed your education goals with your parents or adult relatives?
- E3. Suppose you were to get married right after school, would you want to continue your education after marriage?
- E4. What is the highest level of education you would like to complete if finances and opportunity of the school/college are available?
- E5. What occupation do you expect to have when you are 25 years old?¹⁹

A.4 Gender behavior index

We construct a gender behavior index that measures gender equitable behavior. Questions marked with * are used in the index for girls only, and questions marked with # are coded with opposite signs for boys and girls. The questions used for the baseline behavior index were as follows.

- B1. Are you comfortable talking to children of the opposite gender who are not related to you inside or outside school?
- B2. In the past one week, did you help with cooking/cleaning/washing clothes?#
- B3. Are you allowed to go to the school alone or with friends?*
- B4. During last week were you absent from school?*

The endline behavior index was constructed using the following questions.

Interaction with the opposite sex

- E1. Are you comfortable talking to children of the opposite gender who are not related to you inside and outside school?

¹⁸The question is coded as -1 (gender regressive) if the respondent said 'have no more children' after having two boys but not after having two girls, 1 (gender progressive) if she said 'have no more children' after two girls but not two boys, and 0 otherwise.

¹⁹White collar occupations are coded as more progressive.

E2. Do you sit next to students of the opposite gender in class?²⁰

Participation in household chores

E3. In the past one week, did you cook/clean/wash dishes?#

E4. In the past month, have you missed school due to household based responsibilities?#

Girls' decision-making

E5. I am able to talk to my parents about what work I would like to do in the future.*

E6. Who mostly makes decisions about the following, or if this is in the future for you, who do you expect will make this decision- Will you make the decision, make the decision jointly with parents or will parents make the decision for you?*

- Whether or not you will continue in school past 10th grade
- If you will work after you finish your studies
- What type of work you will do after you finish your studies

E7. During last week how many days were you absent from school?*

Girls' mobility

E8. Are you allowed to go to the school alone or with friends?*

Supporting female relatives' ambitions

E9. Do you discourage your sister/female cousin from working outside home?

E10. Do you discourage your sister/female cousin from studying in college if it is far away?

A.5 Social desirability score

The following questions from Crowne and Marlowe (1960) were asked at baseline with two answer choices: agree or disagree. We use a 13-question short form of the Crowne-Marlowe module developed by Reynolds (1982). The social desirability score sums how many of the responses are the socially desirable one; a low score means a lower tendency to give answers that have social desirability bias.

B1. It is sometimes hard for me to go on with my work if I am not encouraged

B2. I sometimes feel resentful when I don't get my way

B3. On a few occasions, I have given up doing something because I thought too little of my ability

B4. There have been times when I felt like rebelling against people in authority even though I knew they were right

B5. No matter who I'm talking to, I'm always a good listener

B6. There have been occasions when I took advantage of someone

B7. I'm always willing to admit it when I make a mistake

B8. I sometimes try to get even rather than forgive and forget

²⁰This question was not asked in single-sex schools. The value is imputed as the gender-treatment status-district average for these students.

- B9. I am always courteous, even to people who are disagreeable
- B10. I have never been irked when people expressed ideas very different from my own
- B11. There have times when I was quite jealous of the good fortune of others
- B12. I am sometimes irritated by people who ask favors of me
- B13. I have deliberately said something that hurt someone's feelings

A.6 Gender discrimination awareness index

- E1. Do you know about female foeticide and infanticide?
- E2. Are female foeticide and infanticide practiced in Haryana?
- E3. According to you, what is the main reason for female foeticide and infanticide?
- E4. In Haryana, are the number of girls less than the number of boys?

A.7 Self esteem index

- E1. On the whole, I am satisfied with myself
- E2. I feel that I have a number of good qualities
- E3. I am able to do things as well as most other people

A.8 Social norms

The following questions were used to construct our social norms outcome variables. Students were randomized to receive either Set 1 questions or Set 2 questions.

Set 1

- E1. Do you think that people in your village/community think that women should be allowed to work outside home?
- E2. Do you think that people in your village/community think that women should be allowed to work outside home?
- E3. Do you think the community will oppose you since [if] you disagree with them?
- E4. If the community did not oppose you, would you encourage your sister/cousin sister to work outside home after marriage?

Set 2

- E1. Do you think that girls should be allowed to study in college even if it is far away
- E2. Do you think that people in your village/community think that girls should be allowed to study in college even if it is far away?
- E3. Do you think the community will oppose you since [if] you disagree with them?
- E4. If the community did not oppose you, would you encourage your sister/cousin sister to study in college even if it is far away?

A.9 Observed classroom behavior

After analysis of our initially collected data was complete and we had presented our results to some audiences, based on feedback we decided to collect additional data that objectively measured gender-related behaviors in our sample schools. We developed and conducted three activities in the co-ed schools in our sample schools; the activities we developed were appropriate for co-ed schools only. The three activities aimed to measure (1) girls participation in classroom discussions (2) students views about girls knowledge, and (3) interaction with opposite-gender peers in the classroom. In activity (1), a surveyor facilitated a class discussion about "What changes do you want to see in your society?" Another surveyor took note of how many girls and boys made comments in the discussion. In activity (2) students were told about an inter-school competition based on a general knowledge quiz. The winning classroom in each district would get school bags for every student in the class. Students were asked to vote for three students in their class to represent them. The outcome is how many girls are elected for the quiz competition. For activity (3), students were asked to form groups of five to for a poster-making activity about "Swachh Bharat Abhiyan" (India's Cleanliness Drive). The surveyor recorded how many of the groups were mixed-gender.

Appendix Table 12 reports the impact of the intervention on these observed classroom behaviors. Interestingly, for both participation in class discussion and voting for girls to participate in the quiz competition, girls are not underrepresented in the control group. Under the status quo, these are not outcomes where girls are disadvantaged. We find no effect of the intervention. Our final outcome is how many groups of 5 students who self-formed to make posters were mixed-gender. Here, the mean in the control group is strikingly low (5 percent) and the treatment has no detectable impact on this outcome.

There are a few limitations worth noting. First, our pilot sample size was too small to clearly indicate to us that two of our outcomes show no disadvantage for girls. Second, we have low power to detect changes in these outcomes. An ex post power analysis based on the estimated standard errors and control group standard deviation imply that, at 80% power, the minimum detectable effect size is 0.38 to 0.44 standard deviations, which is larger than the estimated effect on our primary outcomes.

A.10 Extended control variables

These variables are used in the LASSO procedure to select the extended controls.

Student-level variables from baseline survey

- Student's age
- Child lives with both his or her mother and father
- Number of sisters
- Number of brothers
- Mother has completed 8th grade
- Mother works part-time
- Mother works full-time
- Scheduled caste
- Scheduled tribe

- Muslim
- Asset variables: House is pukka, House is connected to electricity, Flush toilet, No flush toilet, Family owns the house, Household owns radio or tape recorder, Household owns TV/cable TV/satellite TV/dish TV, Household owns refrigerator, Household gets newspapers daily, Tap water, Household owns water pump
- Self-efficacy score
- Social desirability score
- Parent's gender attitude index²¹

School and village characteristics from other data sources

- Number of full-time teachers
- Number of guest (i.e., temporary) teachers
- Fraction female teachers
- Extracurricular, physical education teachers
- Has school counselor
- PTA meetings
- Frequency of extracurricular activities
- School facilities (Indicators for has library, has toilets, has electricity, has computers, has internet, has sports field, has mid-day meals, has auditorium, has EduSat (satellite-based service delivering educational content))
- Coed versus single sex school
- Rural location
- Village-level adult literacy rate by gender
- Village-level female labor force participation

²¹We include a flag for having parent survey data and impute the value for those without a parent survey.

Appendix Table 13: Extended controls selected for the primary outcomes
